

Long Log Peelers

W.G. Benjey's Long Log Peelers are designed for logs which are too large to be hand fed into a machine by a single person. The largest versions of these machines can easily handle material up to 24" in diameter and 60' in length, though smaller versions are available. Long log peelers come with several options and can be custom designed to meet the customer's needs. Some of these options include: length of machine, cutting head support and travel type, log turning mechanism, and material load and unload method.

With this machine, the work piece is supported at each end by roller saddles. Driven rollers at the head end allow the log to be turned, while the saddles can be raised or lowered to match the size of the log. The tail end saddle can also adjust to any position to best fit the log length. The cutting head is mounted to a space frame that rides on tracks common to the base frame, which allows the head to travel the entire length of the frame. The base frame design also allows the future addition of track sections to extend the total length.

MODEL 2430
30 FT X 18" DIA
CAPACITY

This machine takes a slightly different approach to peeling logs. Instead of the operator working the cutting head along a stationary log, the head is limited to only 14 feet of travel. Driven rollers beneath the log allow it to not only be turned but shuttled left and right. Logs enter the machine from one end and can exit on the other, giving an assembly line effect. Logs of varying length can be used without having to make adjustments. Fewer components make this model a more compact and inexpensive unit, but it has a lower capacity and requires logs to be straighter than other models.

MODEL 2430LLP
60 FT X 24" DIA
CAPACITY

The largest of the long log peelers, this model allows the option of a log turning chuck over the standard driven turning rollers. Adjustable rollers support the log along its length. The cutting head is suspended from tracks that run the entire length of the frame, giving more flexibility and clearance in the working area. This model shown uses the option of a second cutting head, which allows two operators to work on the same log or on two shorter logs simultaneously.
